<sup>3</sup> *Private Company*

# Campo Imperatore

## A site for NIR astronomy

### Location

2154 m a.s.l. near Gran Sasso, Central Appennini, Italy reachable by car during the year and by cableway in winter. Driving time: 1h from Teramo OAAb, 45 min from L'Aquila.

### Site characteristics

- Dark and high-transparency sky
- Dry atmosphere, faint telluric lines between 1 and 2  $\mu\text{m}$
- Low ambient temperatures at nights:
  - down to  $-25\text{ }^{\circ}\text{C}$  during winter
  - $< 15\text{ }^{\circ}\text{C}$  during “hot” summer
- Efficient passive cooling for telescopes and instrumentation.

# A brief history: ATZ24 + SWIRCAM

1997-1999: NIR camera SWIRCAM, equipped with a LN<sub>2</sub>-cooled HgCdTe 256x256 array for a scale of 1"/pixel, designed, built & installed at the focal plane of the AZT24 1.1-m telescope, into the East Dome (*Vitali et al., 2000*).

1998-2018: monitoring & follow-up projects like SWIRT (SNe), WEBT (AGNs) and for an extended set of «smaller» programs concerning stellar variability in the near-infrared (RR-Lyr, Cepheids, LPVs...).

13<sup>th</sup> May 2022: SN2002cv is discovered during the follow-up of SN2002bo in NGC3190 (*Di Paola et al., A&AL 2002*). With  $V-K > 6$ , SN2002cv is one of the most obscured supernovae ever observed.

# A brief history: ATZ24 + SWIRCAM

<b>Optical configuration</b>	f/72. Ritchey-Chrétien

## The CI<sup>2</sup>RCE concept: Campo Imperatore InfraRed Camera with seeing Enhancer

### Refurbishment program:

- Supported by NextGenerationEU funds (PNRR), VITALITY Program
- To be included in the larger program for remote/automated/robotic operations, unmanned operations.

### SWIRCAM system criticalities:

- detector and camera obsolescence;
- LN2 cooling: closed-loop system installed in 2012 to recover N<sub>2</sub>, re-liquify and re-pumping it into the cryostat, BUT...  
... could not be installed onboard the telescope: daily cryostat refilling required anyway manual operations !

### Refurbishment path:

- New detector and camera system, available as COTS on the market (sustainable costs)
- Local cooling (onboard the camera or the telescope), cryogenic or TEC
- Spectral coverage J H K (ideal) or J H (minimum goal)
- Larger format for the array detector wrt SWIRCAM, to cover a FoV wider than 4.4 arcmin
- Enhanced performances by increasing the Strehl Ratio: adaptive correction of the Tip/Tilt
- Reduced instrumental background: telescope secondary mirror resizing (mirrors remanufacturing)

# NIR detector: adopting InGaAs (market) options

SPIE 2014

InGaAs technology proved new developments for ground-based NIR astronomy in the last few years.

Detectors available in several promising formats:

1280 x 1024 pixel

640 x 512 pixel

Typical **pixel sizes** (10 – 15  $\mu\text{m}$ ) much **smaller** than the SWIRCAM pixel size (40  $\mu\text{m}$ ), allow to cover **wider FoV**, with a **reduced background** per pixel and adequate PSF sampling.

**QE much higher** (peak 90%) than for SWIRCAM (peak 65%).

Spectral coverage limited to J and H bands: this limitation can be compensated by the advantages shown above.

With proper detector doping, coverage extended backward down to B V R I optical bands.

## Near-Infrared InGaAs Detectors for Background-limited Imaging and Photometry

### ABSTRACT

Originally designed for night-vision equipment, InGaAs detectors are beginning to achieve background-limited performance in broadband imaging from the ground. The lower cost of these detectors can enable multi-band instruments, arrays of small telescopes, and large focal planes that would be uneconomical with high-performance HgCdTe detectors. We developed a camera to operate the FLIR AP1121 sensor using deep thermoelectric cooling and up-the-ramp sampling to minimize noise. We measured a dark current of  $163 \text{ e}^- \text{ s}^{-1} \text{ pix}^{-1}$ , a read noise of  $87 \text{ e}^-$  up-the-ramp, and a well depth of  $80 \text{ k e}^-$ . Laboratory photometric testing achieved a stability of 230

### Abstract

We describe the results of testing a shortwave infrared CMOS camera using an indium gallium arsenide (InGaAs) detector. The new generation of InGaAs detectors offers a cost-effective alternative to mercury cadmium telluride (HgCdTe) for astronomy research, with current, off-the-shelf cameras requiring no modification before use. Testing was conducted in the laboratory and on-sky while mounted to the robotic, 2 m Liverpool Telescope using a *H*-band filter. The camera exhibits a dark current of  $821 \text{ e}^- \text{ s}^{-1} \text{ pix}^{-1}$  and a bias level of  $864 \text{ e}^- \text{ pix}^{-1}$ . The dark current associated shot noise is of similar size to the read noise of  $32 \text{ e}^- \text{ pix}^{-1}$  in one-second exposures. Linearity within the count region where readout noise and bit-depth saturation effects are not dominant is within a few tenths of a per cent. After field-compression by fore optics, the plate-scale yields  $0.3 \text{ pix}^{-1}$ , near perfect for Nyquist sampling at the La Palma site. The sky background for the *H*-band filter dominates the other noise sources for the

## Wavefront sensing path

### Patrol camera

CMOS detector

FoV 4.5 arcmin

### WFS Quad Cell

Quad cell photodiode  $\approx 1 \text{ mm}^2$  on 2D motor stage

Patrol FoV 4.5 arcmin

## Wavefront sensing & science path

### Advantage

Quad Cell high sensitivity and speed

### Disadvantage

- Opto-mechanical stability
- Semi-‘blind’ pointing (LUTs)

## WFSensing with Patrol Cam

### Advantage

Quad Cell high sensitivity and speed

### Disadvantage

- Opto-mechanical stability
- Semi-‘blind’ pointing (LUTs)

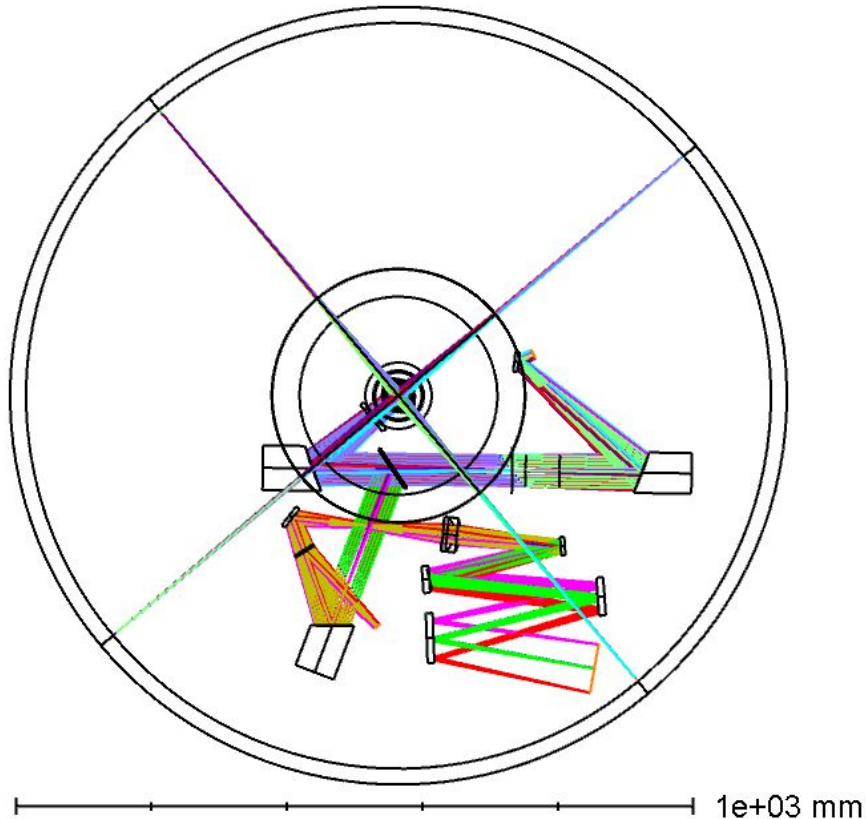

### Depending on sky coverage

- Quad Cell might be removed
- Centroiding on Patrol Camera

# CI<sup>2</sup>RCE Optical Layout

- Design is coplanar
- Leave volume behind the M1 for other instruments
- Folding mirror -> instrument selector

# Preliminary performance estimation

Preliminary “toy-model” to estimate the thermal background from telescope and camera fore-optics.  
 Encouraging results even with overestimated throughputs.  
 Cooling would be only needed for K-band.

Filled area (yellow and red): real throughput from optical elements OL1 and OL2 centers to detector (DET).

Black line, solid: *underestimated* throughput from OL1 center to detector DET (correct for the last OL only (OL2))

Back line, dashed: **overestimated** throughput from OL1 center to detector DET (correct for the last OL only (OL2))

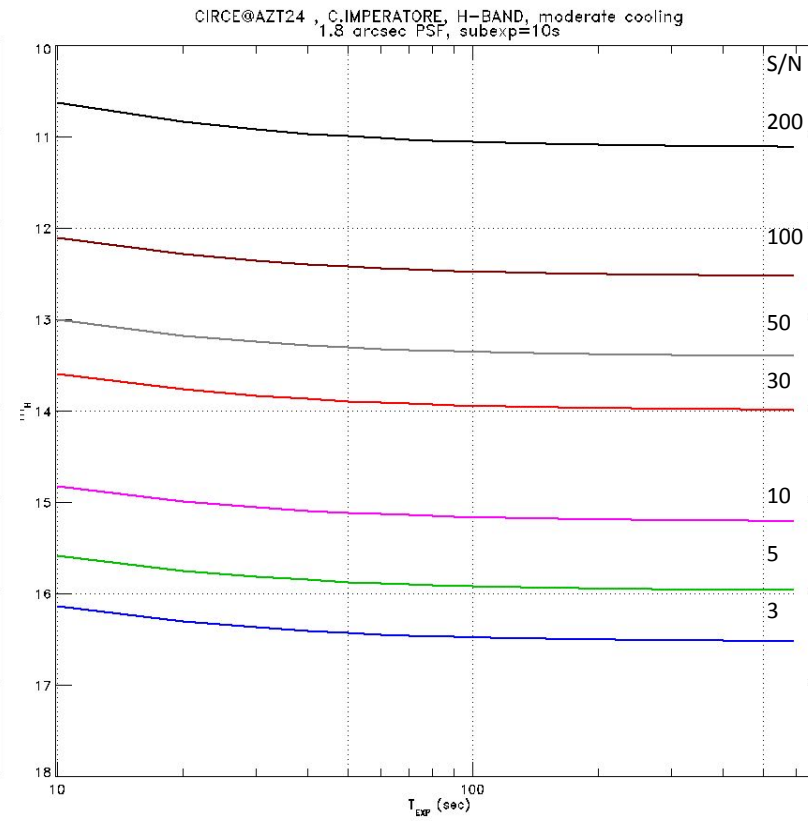

**Magnitude difference 0.9 mag/pixel, about 2 mag/arcsec**

# CI<sup>2</sup>RCE science cases & applications

- Extragalactic transients, GW near infrared counterparts
- Stellar variability (general & GAIA Cepheids for distance calibration)
- NEOs and Jupiter Trojans photometry
- Io's volcanism
- Ground support to space missions, study of the Venus airglow
- Lucky imaging on bright targets
- Machine Learning for sub-noise sources detection.

Emission of the transient SN 2013L (Taddia et al. 2020)

JTs combined VNIR spectra and photometry data.

Venus O2 airglow (Shakun, A. et al. 2023)

# A further step: telescope remanufacturing

## Envisioned changes

- M2 downsized, 590 mm -> 400 mm
- M1 RoC & k (re-)manufacturing
- More compact structure
- Higher throughput
- Lower IR background
- Lighter optomechanics

## First phase - PNRR horizon (end 2025)

- Development of the CI<sup>2</sup>RCE instrument
- Manufacturing and installation of the telescope focal reducer/field corrector
- Integration and alignment of the CI<sup>2</sup>RCE opto-mechanical assembly
- Development and testing of the WFS arm
- First light of CI<sup>2</sup>RCE @ AZT24 and science operations
- **PhD opportunity:** we are looking for a PhD student candidate to support the instrument development (design & WFS).

## Second phase - beyond PNRR horizon - not funded yet

- Manufacturing of the downsized M2
- (Re-)manufacturing of the M1
- Manufacturing and installation of re-adapted telescope focal reducer/field corrector
- CI<sup>2</sup>RCE instrument will be unchanged.

THANK YOU!
